1. We have the recurrence relation in terms of big-oh expressions.

BASIS.
$$T(0) = O(1)$$
.

INDUCTION.
$$T(n) = O(1) + T(n-1)$$
, for $n > 0$.

Here is the recurrence relation now in terms of unknown constants.

Basis.
$$T(0) = a$$
.

INDUCTION.
$$T(n) = b + T(n-1)$$
, for $n > 0$.

We shall now solve this recurrence relation. We determine the sequence

$$T(n) = b + T(n-1)$$

 $T(n-1) = b + T(n-2)$
 $T(n-2) = b + T(n-3)$
...
 $T(1) = b + T(0)$.

Now we can substitute simply. We express T(n) in terms of the value of T(n-1) and get

$$T(n) = b + (b + T(n-2)) = 2b + T(n-2).$$

And again, T(n) expressed in terms of the value of T(n-2) to get

$$T(n) = 2b + (b + T(n - 3)) = 3b + T(n - 3).$$

This should suffice to capture the pattern. We see that, in terms of i, we have

$$T(n) = ib + T(n - i).$$

Where i = n, we will have expressed T(n) in terms of the basis T(0). This is

$$T(n) = nb + T(0) = nb + a.$$

Now we express T(n) back in terms of big-oh expressions. The term nb is n proportional to some constant and a is only proportional to a constant. Thus the terms are O(n) + O(1). Therefore the running time of sum is O(n).

2. A suitable size measure is the length of the list input.

BASIS.
$$T(0) = T(1) = O(1)$$
.

INDUCTION.
$$T(n) = O(1) + T(n-1)$$
, for $n > 1$.

Rewriting this in terms of unknown constants we have

BASIS.
$$T(0) = T(1) = a$$
.

INDUCTION.
$$T(n) = b + T(n-1)$$
, for $n > 1$.

Let us find a pattern. We have

$$T(n) = b + (b + T(n-2)) = 2b + T(n-2).$$

That is good enough. We determine that

$$T(n) = ib + T(n - i).$$

To express T(n) in terms of T(1), substitute i for n+1. Then we have

$$T(n) = (n+1)b + T(n-(n+1)) = (n+1)b + T(1) = (n+1)b + a.$$

We have a function proportional to n and a function proportional to a constant. The two terms expressed as big-oh expressions are O(n) + (1), and O(n) is the running time of find0.

3. A suitable size measure is m = n - i, the number of elements still unsorted.

BASIS.
$$T(1) = O(1)$$
.

INDUCTION.
$$T(m) = O(m) + T(m-1)$$
, for $m > 1$.

We substitute for constants.

BASIS.
$$T(1) = a$$
.

INDUCTION.
$$T(m) = bm + T(m-1)$$
, for $m > 1$.

By substitution we try to discover a pattern

$$T(m) = bm + T(m-1)$$

$$= bm + b(m-1) + T(m-2) = b(2m-1) + T(m-2)$$

$$= b(2m-1) + b(m-2) + T(m-3) = b(3m-3) + T(m-3)$$

$$= 3b(m-1) + b(m-3) + T(m-4) = b(4m-6) + T(m-4)$$

$$= b(4m-6) + b(m-4) + T(m-5) = b(5m-10) + T(m-5).$$

Now we see the pattern. It is

$$T(m) = b \left(km - \sum_{j=1}^{k-1} j \right) + T(m-k) = b(km - k(k-2)/2) + T(m-k).$$

Let k = m - 1. Then we have T(n) expressed in terms of T(1) and also with k in terms of m, which is

$$T(m) = b \left((m-1)m - \sum_{j=1}^{m-2} j \right) + T(1)$$

$$= b((m-1)m - (m-2)(m-2+1)/2) + a$$

$$= b((m-1)m - (m-2)(m-1)/2) + a$$

$$= b((m-1)(m - (m-2)/2)) + a$$

$$= b((m-1)((2m-m+2)/2)) + a$$

$$= b((m-1)((m+2)/2)) + a$$

$$= b(m-1)(m+2)/2 + a.$$

If we multiply we will get a m^2 term. Thus the recursive selection sort program is $O(m^2)$.

4.

BASIS.
$$T(1) = T(2) = O(1)$$
.

INDUCTION.
$$T(n) = O(1) + T(n-1) + T(n-2)$$
, for $n > 2$.

We substitute for constants.

BASIS.
$$T(1) = T(2) = a$$
.

INDUCTION.
$$T(n) = b + T(n-1) + T(n-2)$$
, for $n > 2$.

We try to find a pattern

$$\begin{split} T(n) &= b + T(n-1) + T(n-2) \\ &= b + (b + T(n-2) + T(n-3)) + (b + T(n-3) + T(n-4)) \\ &= b + (b + (b + T(n-3) + T(n-4)) \\ &+ (b + T(n-4) + T(n-5))) \\ &+ (b + (b + T(n-4) + T(n-5)) \\ &+ (b + T(n-5) + T(n-6))). \end{split}$$

The relation between the inputs of T has the pattern

n-1

n-2

with the next being

n-2

n-3 n-3

n-4

and the next being

n-3

n-4 n-4 n-4

n-5 n-5 n-5

n-6

The pattern to capture so far is that the number of T terms double starting from 2, the number of b terms is one less than the number of T terms, the number of rows and columns increases by 1, the greatest n-i term decreases by 1 and the least n-i term decreases by 2. The number of terms on each row resembles the corresponding binomial coefficient.

Thankfully we do not have to discover a method of computing the coefficients. We need only relate this problem to another. Let k be the least i in all the T(n-i) terms, then we have

$$T(n) = (2^{k} - 1)b + \sum_{j=k}^{2k} {k \choose j-k} T(n-j).$$

But based on the pattern and with k = n - 2 we can write

$$(2^{n-2}-1)b+$$

5. Since j is not constant we will use m to represent whatever that value is.
